Executive Summary

This report describes the Third Quarter 2014 groundwater monitoring event completed at the Playa Vista property (the Site) located in Los Angeles, California. Included in this report are summaries of groundwater analytical results, an update of activities conducted, and recommendations for next quarter's activities. In addition, appendices to this report include information on historical Site investigation and remedial activities, field procedures and documentation, as well as laboratory reports and data quality assurance/quality control evaluation. Information directly relevant to this quarter's sampling are provided in the text portion of the report, while supporting background information as well as historical data are presented in the appendices for reference.

Between July 1 and September 9, 2014, CDM Smith Inc. (CDM Smith) conducted the quarterly groundwater monitoring event in which groundwater elevations were measured at 244 monitoring wells and samples were collected from 239 monitoring and remediation system wells located throughout the Site and screened in the Bellflower aquitard, and the Ballona and Silverado aquifers, the three primary water-bearing zones beneath the Site. Additionally, six surface water samples were collected from the Riparian Corridor to monitor water quality at locations adjacent to historical source areas.

During this round of monitoring, no significant changes or unusual findings were reported. Recommendations for upcoming activities include continued operation of the groundwater treatment systems at the former Fire Safety Training Area (FSTA), Area D2, and the Campus Area, and continued assessment at monitoring and remediation system wells located throughout the Site.

Section 1
Introduction

CDM Smith has prepared this *Third Quarter 2014 Groundwater Monitoring Report* on behalf of Playa Capital Company, LLC (Playa). This report describes the activities and presents the results of the recent groundwater monitoring event completed at the Playa Vista property (the Site) located in Los Angeles, California. Included are groundwater analytical results, an update of activities conducted, and recommendations for next quarter activities. In addition, appendices to this report include background information related to areas of concern at the Site, field procedures and documentation, historical data, as well as laboratory reports and data quality assurance/quality control evaluation.

1.1 Report Overview

CDM Smith has prepared this report in accordance with the Cleanup and Abatement Order (CAO) No. 98-125 (File No. 98-192) (Regional Water Quality Control Board – Los Angeles Region [RWQCB], 1998), the *Groundwater Sampling and Analysis Plan (SAP), Area D - Playa Vista Site* (Camp Dresser & McKee Inc. [CDM], 2003a), modifications to the SAP (CDM, 2004a), the proposed groundwater monitoring schedule for 2006 that was presented in the *Fourth Quarter of 2005 Groundwater Monitoring and Progress Report* (CDM, 2006a),[1] and recommendations for 1,4-dioxane monitoring presented in the *Fourth Quarter 2010 Groundwater Monitoring Report, Playa Vista* (CDM, 2011a). The 2006 groundwater monitoring schedule was conditionally approved by RWQCB on January 27, 2006 (RWQCB, 2006).

Remediation progress reports are submitted separately for the former Test Site 2 (TS2) Area, former Fire Safety Training Area (FSTA), Area D2, and the Campus Area. Section 2 of this quarterly monitoring report presents the sampling results for the second quarter of 2014. Section 3 summarizes the results, and Section 4 presents a third 2014 progress update and discusses activities and recommendations proposed for the fourth quarter of 2014. Sections 5, 6 and 7 include references, figures, and tables, respectively. As a measure to increase sustainability, all appendices of this report will be provided in electronic format on the enclosed compact disk (CD).

1.2 Site Description

The Site currently consists of approximately 460 acres of land in the western portion of the City of Los Angeles, Los Angeles County, California. The Site is located north of the Los Angeles International Airport and, at its nearest point, is situated approximately 1.5 miles east of the Pacific Ocean. Marina del Rey is located directly northwest of the Site (Figure 1).

[1] Although the proposed 2006 groundwater monitoring schedule was intended as a sampling and analysis plan for the 2006 calendar year, this plan has been utilized as a guidance document for the most recent sampling activities that occurred in this third quarter of 2014.

The Site is currently being developed in two phases and is the subject of this report (Figure 2). Development in the western portion of the Site, Phase 1 area, is nearing completion. This area is a mixed-use community with a blend of residential, retail, office, community-serving, and recreational uses. The former FSTA and TS2 are located within this area and are currently undergoing remediation. The eastern portion of the Phase 1 area, or the Campus Area, is being developed for commercial, retail, and recreational uses.

The second phase (Phase 2) of development in Area D (Area D2), or the Village at Playa Vista, is envisioned to be a mixed-use community including residential, office, retail, community-serving, and recreational uses, as well as open space. Portions of the Phase 2 area are currently under construction.

1.3 Monitoring Well Summary

Groundwater wells installed and sampled at the Site are screened within three distinct water-bearing zones (discussed in Appendix A) as follows:

- The shallowest zone classified as the Bellflower aquitard including the upper zone characterized by fine-grained silts and clays and the lower zone characterized by slightly more permeable silts and sands.
- The underlying and more permeable Ballona aquifer.
- The Silverado aquifer, which is the deepest zone sampled.

Groundwater investigations began in 1983 with the installation of the first monitoring wells. Over the years, more than 470 monitoring and remediation system wells have been installed (excluding temporary monitoring wells) across the Site, although some have been destroyed or abandoned over time due to Site remediation or development activities or are no longer monitored. Currently, approximately 300 monitoring and remediation system wells are included in the groundwater sampling network and are sampled at least annually, but most are sampled quarterly or semi-annually as shown on Table 1.

1.4 Scope of Work

The scope of work for the second quarter 2014 groundwater monitoring event included the following tasks:

- Measure depth to groundwater in 244 monitoring wells;
- Purge and collect groundwater samples from 239 monitoring and remediation system wells;
- Collect surface water samples at six locations within the Riparian Corridor
- Analyze all samples for volatile organic compounds (VOCs) and selected groundwater samples for other parameters;
- Evaluate the data; and
- Prepare this quarterly monitoring report.

Section 2
Data Presentation and Summary of Results

The third quarter 2014 quarterly groundwater monitoring event was conducted between July 1 and September 9, 2014. Groundwater sampling was performed at 239 groundwater monitoring and remediation system. Surface water samples were also collected at six locations within the Riparian Corridor. Water level gauging was conducted at 244 monitoring wells.

Groundwater elevation and water quality results for the third quarter 2014 are discussed in this section. Field procedures and equipment used to conduct field activities during this groundwater sampling event are presented in Appendix C of this report. Groundwater sampling activities were performed in accordance with the 2006 Groundwater Monitoring Schedule and CDM Smith Health and Safety Plan (HASP) for the Site (CDM, 2006b). CDM Smith subcontracted Blaine Tech Services Inc. to assist with well purging and groundwater sampling. A CDM Smith geologist was present during sampling and provided oversight throughout the sampling period. Field data forms completed during water level measurement and monitoring well purging and sampling are contained in Appendix D.

For reference: construction details and status of monitoring wells are summarized in Table 1; Table 2 lists the wells gauged during the third quarter 2014 sampling event; a summary of the sampling matrix is provided in Table 3; and, analytical methods and preservatives are summarized in Table 4.

Based on the results from the third quarter 2014 samples, no significant changes or unusual findings in groundwater flow or quality were noted during this event. Findings from the third quarter 2014 monitoring event are summarized below.

2.1 Groundwater Elevations and Flow

In total, 244 wells were gauged during the third quarter of 2014 as listed in Table 2 and groundwater elevation data from this quarter are summarized in Table 5. For reference, hydrographs graphically illustrating the historical fluctuations in water levels during the quarterly monitoring events are presented in Appendix E (Figures E-1 through E-26) and historical groundwater elevation data are included for reference in Appendix F. Groundwater elevations and flow directions for wells screened within the Bellflower aquitard, and Ballona and Silverado aquifers are illustrated in Figures 3A and 3B, 4, and 5, respectively. Groundwater elevations and flow directions, according to their hydrostratigraphic units, are summarized in the following paragraphs.

Bellflower aquitard: Groundwater elevations were measured at 169 wells located throughout the Site and ranged from -0.52 feet mean sea level (MSL) (in the Campus Area) to a maximum of 9.80 feet MSL (in the Phase 1 Residential Area). When compared to second quarter 2014 data, groundwater elevations were variable with some higher and some lower than last quarter, however, most were lower.

Consistent with prior events, the overall groundwater flow across the Site is quite variable in the Bellflower aquitard and is significantly influenced by groundwater extraction in areas of active remediation. Groundwater in the Bellflower aquitard exhibited a north to northwesterly flow, except at those locations close to groundwater extraction wells where groundwater exhibited radial flow toward extraction wells in the Campus Area and interceptor trenches at FSTA.

Ballona aquifer: Groundwater elevations were measured at 61 wells during this event and ranged from 1.84 feet MSL (in the Campus Area) to 6.00 feet MSL (in the western portion of the Site). When compared to last quarter's data, groundwater elevations decreased slightly or remained essentially the same in Ballona aquifer wells. Groundwater elevations at all Ballona aquifer wells have shown an overall gradual increase since 1999; however, this increasing trend appears to have peaked during the first quarter of 2006, followed by a relatively stable trend since the first quarter of 2007.

Groundwater flow is generally to the north and west in the eastern portion of the Campus Area and to the north, away from the Westchester Bluffs, in the central and western portions of the Site. Multi-direction or radial flow is observed in the vicinity of the Campus Area extraction wells where active remediation is occurring.

Silverado aquifer: Groundwater elevations were measured at 14 wells located throughout the Site and ranged from 0.44 feet MSL (in the eastern portion of the Campus Area) to 6.12 feet MSL (in the former FSTA). Groundwater elevations decreased in all Silverado wells, except one where a slight increase (0.25 foot) was noted, when compared to last quarter's data. A gradual increasing trend in groundwater elevations has been reported in Silverado aquifer wells located in the Campus Area since 1999; however, this increasing trend appears to have become less pronounced over the last several years.

Groundwater flow is to the north to northwest. It should be noted that, beginning in the third quarter of 2012, the direction of groundwater flow in the eastern portion of the Site began showing a northerly flow, which is different than the southwesterly flow direction that developed in approximately 2004 to 2005.

2.2 Field Screening Results

The following groundwater quality parameters were monitored during well purging activities: oxidation reduction potential (ORP), electrical conductance (EC), temperature, pH, turbidity and dissolved oxygen (DO). Due to the difficulty of accurately measuring DO concentrations, DO was measured using three methods: a downhole DO meter prior to purging, a DO probe and flow-through cell during purging, and Chemets® DO ampoules at the end of the purge cycle. The field screening data from the third quarter 2014 monitoring event are summarized in Table 6. Historical field screening results are included in Appendix G for reference.

In addition to the parameters mentioned above, hydrogen sulfide, ferrous iron, and carbon dioxide were also measured in the field at select wells using Hach® test kits and

methods as outlined in Table 4. These parameters were analyzed in accordance with the TS2, the Campus Area, and the FSTA Monitoring and Contingency Plans (MCPs) to monitor the performance of the remediation systems. In addition, several other analyses were performed to assist with the monitored natural attenuation (MNA) evaluation and are summarized in Table 7. All field and laboratory results will be discussed as part of the overall system performance in the *Test Site 2 Third Quarter 2014 Remediation System Progress Report*, the *Campus Area Third Quarter 2014 Remediation System Progress Report,* the *Area D2 Third Quarter 2014 Remediation System Progress Report,* and the *Former Fire Safety Training Area Third Quarter 2014 Remediation System Progress Report.* These reports will be submitted at a later date under separate cover.

2.3 Groundwater Analytical Results

In total, 239 groundwater wells were sampled during the third quarter of 2014 and analyzed in accordance with the matrix listed in Table 3. Specifically, all groundwater samples were analyzed for VOCs using the United States Environmental Protection Agency's (USEPA's) Method 524.2, and for other parameters as specified in Table 3. In addition, select groundwater samples were analyzed for 1,4-dioxane using EPA Method 8270M, in accordance with Table 14 of the *Fourth Quarter 2010 Groundwater Monitoring Report*, Playa Vista (CDM, 2011a) to monitor 1,4-dioxane concentrations throughout the Site. Analytical methods and preservatives are summarized in Table 4. Analytical results from this quarter are summarized in Tables 8 through 11 and historical data are included for reference in Appendix G.

Third quarter 2014 groundwater data were used to generate isoconcentration maps showing the approximate extent of cis-1,2-dichloroethene (cis-1,2-DCE), vinyl chloride, and 1,4-dioxane in the Bellflower aquitard and Ballona aquifer (Figures 6 through 11). Cis-1,2-DCE and vinyl chloride were selected because they have been historically detected the most frequently and at the highest concentrations in groundwater samples. Isoconcentration maps showing 1,4-dioxane levels were generated to monitor the lateral and vertical extent of this contaminant. Groundwater quality charts illustrating historical trends in total VOC concentrations are included in Appendix H and trend charts for four of the most frequently detected and representative analytes (1,1-dichloroethane [1,1-DCA], cis-1,2-DCE, trichloroethene [TCE] and vinyl chloride) are included in Appendix I. It should be noted that Appendices H and I only include trend charts for those wells sampled during this third quarter 2014 monitoring event. Laboratory analytical reports for the third quarter 2014 sampling event are included in Appendix J.

Groundwater quality data, according to their hydrostratigraphic units, are summarized in the following paragraphs.

2.3.1 Bellflower Aquitard

VOCs: A total of 181 remediation system and monitoring wells screened in the Bellflower aquitard were sampled during the third quarter of 2014 and analyzed for VOCs. Cis- and trans-1,2-DCE, vinyl chloride, 1,1-DCA, and 1,1,1-trichloroethane (1,1,1-TCA) were the most prevalent VOCs detected in Bellflower aquitard wells.

1,4-Dioxane, a non-chlorinated VOC, was detected in 50 of the 82 wells sampled for this compound at concentrations greater than California's drinking water notification level of 1.0 µg/L. Of the wells where 1,4-dioxane was detected, 13 had concentrations that exceeded California's response level of 35 µg/L. Notification levels are health-based advisory levels for compounds that lack MCLs and response levels are the levels at which a drinking water source is recommended to be removed from service. It should be noted that the Bellflower aquitard is not a source of drinking water.

The highest VOC concentrations were localized within the source areas of the Campus Area, with the highest total VOCs reported in source areas SA-1, SA-4, SA-5, and SA-9, consistent with previous data. VOC concentrations in wells located throughout the Site are variable, with some concentrations higher (54 percent) and some approximately the same or lower (46 percent) this quarter when compared to last quarter's data. The greatest fluctuations were noted at remediation system wells in the Campus Area. Variable concentrations within remediation areas are to be expected as groundwater contamination is drawn towards the extraction wells.

Total Petroleum Hydrocarbons (TPH): Groundwater samples collected from two monitoring wells in Area D2 were analyzed for TPH. As shown on Table 10, TPH was detected at a concentration slightly higher than the laboratory reporting limit in one well, D2-UBe13. TPH concentrations were approximately the same or higher (D2-UBe13) when compared to last quarter's results.

Metals: In addition to VOCs, 14 wells screened in the Bellflower aquitard were sampled this quarter and analyzed for chromium compounds and an additional 13 wells were analyzed for the entire suite of California Administrative Manual (CAM) 17 metals. Of the metals, only arsenic, lead, and/or nickel were detected in any of the Bellflower aquitard wells at concentrations exceeding California MCLs. It should be noted that the detected concentrations were within a range historically reported and only slightly higher than their respective MCLs. Analytical results are summarized in Table 11.

2.3.2 Ballona Aquifer

VOCs: In total, 55 wells screened in the Ballona aquifer and located throughout the Site were sampled this quarter and analyzed for VOCs (Tables 8 and 9). The frequency and magnitude matches that detected in the overlying Bellflower aquitard where cis-1,2-DCE, vinyl chloride, and 1,1-DCA were the most prevalent VOCs reported with highest concentrations detected in the Campus Area near or downgradient of the former source areas.

1,4-Dioxane, a non-chlorinated VOC, was detected in 22 of the 36 wells sampled for this compound at concentrations greater than California's drinking water notification level of 1.0 µg/L. Of the wells where 1,4-dioxane was detected, none had concentrations exceeding California's response level of 35 µg/L.

The areal extent of VOC contamination in the Ballona aquifer is broader than in the Bellflower aquitard throughout the Site but the concentrations are orders of magnitude lower. When compared to last quarter's results, total VOC concentrations in Ballona aquifer wells were variable with some wells

demonstrating increases (45 percent) while other wells remaining approximately the same or demonstrating decreases (55 percent).

Metals: In addition to VOCs, two wells screened in the Ballona aquifer and located the Campus Area were sampled this quarter and analyzed for chromium compounds. Two newly-installed wells in the Campus Area were analyzed for the entire suite of CAM 17 metals. No metals were detected above California MCLs.

2.3.3 Silverado Aquifer

Three wells screened in the Silverado aquifer and located in the vicinity of TS2 and Area D2 were sampled for VOCs this quarter. No VOCs were detected at concentrations above California MCLs. When compared to last quarter's data, concentrations were approximately the same or just slightly higher.

2.4 Surface Water Analytical Results

Surface water samples were collected from the Riparian Corridor at three locations near the former FSTA in the Phase 1 residential area and at three locations near the former salvage yard and firing range in Area D2. The locations were selected to monitor water quality conditions within the lined portions of the Riparian Corridor adjacent to these areas, and in the unlined portion of the Riparian Corridor both upgradient and downgradient of these areas. Surface water samples were analyzed for VOCs, including 1,4-dioxane. Results are summarized on Tables 8 and 9. Detectable concentrations of VOCs (acetone, carbon disulfide, and/or toluene) were detected in four of the surface water samples. Except for acetone in one sample, all concentrations were low and just slightly greater than laboratory reporting limits. Because these constituents are common laboratory contaminants, it is likely that their presence is from laboratory procedures and is not considered significant. However, results of future monitoring events will be monitored for potential trends.

2.5 Quality Assessment of Data

A number of quality assurance/quality control (QA/QC) measures were employed in the field to ensure that the collected groundwater samples were of known quality in support of the data quality objectives (DQOs) developed for the project. Field QA/QC samples were collected and tested to provide quality control checks on the representativeness of the environmental samples collected, the accuracy and precision of sample analyses, and sample handling procedures. The following field QC samples were collected during this groundwater sampling event: duplicate groundwater samples and equipment decontamination and trip blanks.

2.5.1 Duplicate Samples

Analytical results of the environmental samples and their duplicates (indicated as "K" samples) are presented on Tables 7 through 11. In total, 25 split groundwater samples (i.e., 25 sample pairs) were collected during the third quarter 2014 sampling event, which equates to approximately 10 percent of the total number of samples collected. Duplicate samples were analyzed for the same parameters as the primary samples. Data obtained from field duplicate samples provide an estimate of laboratory and field precision.

For 88 percent of the sample pairs (22 out of 25 sample pairs), the detected concentrations between the groundwater samples and their duplicates were within 25 percent of each other for all analytes. In the remaining 12 percent of the duplicate sample pairs, the 25 percent criterion was exceeded, however, the concentrations of the detected analytes were very low (within five times the reporting limit) or within the same order of magnitude. Therefore, qualification as a result of the precision deficiencies was not warranted.

2.5.2 Equipment and Trip Blanks

Equipment blanks were collected to evaluate potential cross-contamination from sampling equipment. Equipment blanks were collected by pouring "blank" water through the sampling equipment and then collecting the rinsate in appropriate sample containers following equipment decontamination. Laboratory-provided, purified water (purged and deionized) was used as the "blank" water for equipment blanks.

In total, 20 equipment blanks were collected during the third quarter 2014 sampling event, which represents a target collection frequency of one equipment blank per day of sampling. All equipment blanks were analyzed for VOCs and select blanks were also analyzed for 1,4-dioxane, TPH, and metals, if wells were sampled for those constituents on that day. Except for 1,4-dioxane, cis-1,2-DCE, carbon disulfide, and methylene chloride, no other VOCs were detected in any of the equipment blanks at concentrations greater than laboratory reporting limits. In each case where a contaminant was detected in an equipment blank, the corresponding concentrations in the project samples were either non-detectable or greater than five times the concentration detected in the blanks. Although the presence of VOCs in the equipment blanks suggests that decontamination procedures were not completely effective, the detections do not impact the usability of the project data.

Trip blanks were collected to evaluate the potential for cross-contamination during sample transport, shipment and storage. Trip blanks consisted of organic-free water that is transported from the analytical laboratory to the Site, and then returned to the laboratory along with the field samples without being opened. Trip blanks were submitted to the laboratory for analysis if VOCs were detected in the corresponding equipment blanks or if no other blank was collected on that day (i.e., when extraction wells were sampled). No constituents were detected in any of the trip blanks at concentrations greater than laboratory reporting limits, which demonstrate that cross-contamination did not occur.

2.5.3 Laboratory QA/QC

Analytical data generated during the third quarter 2014 groundwater sampling event were reviewed and evaluated to ensure that they were usable and met the project objectives. USEPA's Contract Laboratory Program National Functional Guidelines for Organic and Inorganic Data Review (USEPA, 2004 and 2008) were used to assess overall analytical data quality.

Laboratory data were reviewed for inclusion and frequency of the necessary QC supporting information. Supporting QC documentation that was evaluated for each analytical report included the following major items:

- sample holding times
- method blanks
- matrix spike/matrix spike duplicate (MS/MSD) recoveries
- relative percent difference (RPD) between MS and MSD
- laboratory control sample (LCS) recoveries
- surrogate spike recoveries

The review included data generated by Associated Laboratories (Associated), located in Orange, California, and Pace Analytical (formerly Microseeps), located in Pittsburgh, Pennsylvania. Table 12 summarizes the number of samples, type of samples, and analytical methods performed by Associated and Pace Analytical. Associated is certified by California's Environmental Laboratory Accreditation Program (ELAP Certification number 1338). Analyses performed by Pace Analytical are not regulated by ELAP. Therefore, certification is not applicable. A summary of the findings of the data evaluation is included in Appendix K.

Analytical reports were reviewed and evaluated to assess the overall quality and usability of the project data. All data were considered usable and meet the project objectives.

Section 3
Progress Update and Recommendations

This section presents an update of activities conducted during the third quarter of 2014 and proposed for the fourth quarter of 2014 at the Site.

The following activities were conducted during the third quarter of 2014:

- Phase 1 - Former FSTA: Continued groundwater extraction at FSTA EW-5.
- Phase 1 - Former TS2: Continued the third rebound testing phase in accordance with recommendations in the *Fourth Quarter 2011 Test Site 2 Remediation Progress and Waste Discharge Requirements Report* (CDM Smith, 2012a).
- Phase 1 - Former TS2: Submitted a request to cease groundwater extraction and re-injection and decommission the groundwater treatment system at TS2 (CDM Smith, 2014h).
- Phase 1 – Former TS2: Abandoned the three PZ-3 wells and began excavation of three areas of impacted soil in accordance with RWQCB's conditional approval of the *"No Further Action" Determination for Unsaturated Soils, Former Test Site 2* (RWQCB, 2014a). The PZ-3 wells were immediately adjacent to one of the excavations and, with RWQCB approval (RWQCB, 2014c), were abandoned prior to excavation to ensure proper abandonment.
- Phase 1 – Bluff Creek Drive, North of School Site in Tract 49104 Lot 6: Sampled groundwater monitoring well C-162 during the third quarter of 2014 as part of continued monitoring to assess VOC concentrations in groundwater adjacent to the school site.
- Phase 1 – School Site: Measured groundwater elevations and collected groundwater samples from eight groundwater monitoring wells during the third quarter of 2014.
- Phase 1 – Bluff Creek Drive, North of School Site in Tract 49104 Lot 6: Continued with remedial design activities.
- Phase 1 – Campus Area: Continued operation of the groundwater and vapor extraction portions of the remediation system.
- Phase 1 – Campus Area: Conducted optimization activities at select remediation system extraction wells.
- Phase 1 – Campus Area: Re-installed five monitoring wells located in Tract 49104-04 of the Campus Area in accordance with CDM Smith's work plan (CDM Smith, 2014e), and RWQCB approval (RWQCB, 2014b).

- Phase 1 – Campus Area: Installed three monitoring wells and re-installed one damaged well in accordance with the revised *Work Plan to Assess Potential Groundwater Impacts of Test Pile Installation, Parcel 10* (CDM Smith, 2014d) and RWQCB's approval of the revised work plan on June 4, 2014 (RWQCB, 2014c).

- Phase 1 - Campus Area: Submitted the test pile monitoring well installation report (CDM Smith, 2014i).

- Phase 1 – Campus Area: Submitted *Addendum Number 1, Data Gap Evaluation Report and Work Plan, Phase 1 Campus Area, Playa Vista Site* (Hargis + Associates [Hargis], 2014b).

- Phase 2 – Continued operation of the Area D2 remediation system.

- Phase 2: Performed optimization activities at the two existing remediation system extraction wells (D2-RW1LBe and D2-RW2LBe).

- Phase 2: Installed two remediation system extraction wells (D2-RW3LBe and D2-RW4LBe) and successfully incorporated them into the existing groundwater remediation system.

- Phase 2: Conducted soil vapor study of proposed restroom location in Bluff Creek Park.

- Site-wide: Conducted the third quarter 2014 Site-wide quarterly groundwater monitoring event. This sampling event incorporated the recommendation presented in the fourth quarter of 2010 monitoring report to sample select monitoring wells for 1,4-dioxane.

Activities scheduled or planned for the fourth quarter of 2014 (October through December) include the following tasks:

- Site-Wide: Implement fourth quarter 2014 Site-wide quarterly groundwater monitoring event.
- Site-Wide – Submit proposed modifications to the quarterly groundwater monitoring program, which will update and replace proposed changes previously submitted to RWQCB in September 2010.
- Phase 1 – Former FSTA: Continue operating the groundwater extraction system. Activities planned for the fourth quarter of 2014 will be submitted at a later date under a separate cover in the *Former Fire Safety Training Area Third Quarter 2014 Remediation Progress Report.*
- Phase 1 - Former TS2: Continue third round of rebound testing. Conduct groundwater monitoring activities as part of Site-wide monitoring to provide assessment of the effectiveness of the additional EOS injections. Evaluation and results will be submitted at a later date under a separate cover in the *Third Quarter 2014 Test Site 2 Remediation System Progress Report.*

- Phase 1 – Former TS2: Continue excavating and then backfill three areas of impacted soil in accordance with RWQCB's conditional approval of the *"No Further Action" Determination for Unsaturated Soils, Former Test Site 2* (RWQCB, 2014a). Submit technical report documenting remedial activities. Remove deed restriction.
- Phase 1 Bluff Creek Drive, north of School Site in Tract 49104 Lot 6: Although VOC concentrations continue to demonstrate a decreasing trend, the concentrations still exceed MCLs for several compounds. As such, continued quarterly monitoring of well C-162 is recommended to continue to monitor the trend.
- Phase 1 – Bluff Creek Drive, North of School Site in Tract 49104 Lot 6: Submit Addendum to *Remedial Action Plan for the Off School Site Area* and continue with remedial design.
- Phase 1 – Bluff Creek Drive, North of School Site in Tract 49104 Lot 6: Install remediation system extraction well OSS EW-1 and related conveyance lines and conduits, if school and remedial design schedules allow installation during school's winter break.
- Phase 1 - Campus Area: Continue groundwater extraction and vapor extraction. Activities planned for the fourth quarter of 2014 in the Campus Area will be submitted under a separate cover in the *Campus Area Third Quarter 2014 Remediation System Progress Report*.
- Phase 1 – Campus Area: Submit *Addendum Number 2, Data Gap Evaluation Report and Work Plan, Phase 1 Campus Area, Playa Vista Site*.
- Phase 1 – Campus Area: Submit technical report documenting re-installation of five monitoring wells located in Tract 49104-04 of the Campus Area.
- Phase 2 – Continue operations of the Area D2 remediation system. Activities planned for the fourth quarter of 2014 in Area D2 will be submitted under a separate cover in the *Area D2 Third Quarter 2014 Remediation System Progress Report.*
- Phase 2 - Submit technical report documenting soil vapor study at proposed restroom in Bluff Creek Park.

Notes:

Wells shown on table include those that have been historically sampled and/or gauged by CDM.
MSL = Mean sea level
Sampling Frequency:
Quarterly - groundwater samples are collected in the 1st, 2nd, 3rd and 4th quarters each year
Semi-Annual - groundwater samples are collected in the 2nd and 4th quarters each year
Annual - groundwater samples are collected in the 4th quarter each year

Notes:

● = Parameter for quarterly sampling. Quarterly sampling was conducted in accordance with the Groundwater Sampling and Analysis Plan (SAP, dated February 3, 2003), Campus Area PMCP (March 31, 2003), FSTA and TS2 MCP (December 21, 2009).

☒ = Additional parameter specified in Waste Discharge Permit under Order No. R4-2002-0030 that is not in TS2/FSTA MCP.

☐ = Vapor and groundwater sample collected from DPE well

Analyses were performed by Associated Laboratories, a fixed based laboratory located in Orange, CA, except where noted below.

Methane, ethane, and ethene, dissolved hydrogen, and metabolic acids analyses will be performed by Pace (formerly Microseeps) of Pittsburgh, PA.

Ferrous iron, carbon dioxide, and hydrogen sulfide will be analyzed immediately after sample collection by onsite personnel using a Hach equipment.

Trip blanks were submitted at a frequency of one per day, but were placed on hold pending results of the equipment blank analysis.

Aquifer

UB = Upper Bellflower

LB = Lower Bellflower

BE = Bellflower (undesignated)

BA = Ballona

SI = Silverado

Table 4
Summary of Testing Methods, Containers, Preservatives and Holding Times
Third Quarter 2014 Groundwater Monitoring Report

	Parameter	Recommended Instrument	Analytical Method	Container Requirement	Field Filtered (Y/N)	Preservative	Holding Time
Field Parameters	Oxidation-Reduction Potential (ORP)	Flow-thru cell	DRI	N/A	N	N/A	ASAP

If left blank, the parameter was not measured.
NTUs = Nephelometric Turbidity Units
umhos/cm = micromhos per centimeter
mg/L = milligrams per liter
mV = millivolts
* Well dewatered before parameters stabilized or before minimum purge volume was reached
** Reading appears anomalous. Some negative DO readings may be a result of H2S interference in older flow-thru cells.

All wells were purged with a 2-inch Grundfos pump except where noted.
B = Well was purged with a disposable bailer.
W = Well was purged using a Waterra pump.
BL = Well was purged with a bladder pump.
LF = Low-flow purge method
NS = Not Sampled
H = Hand check
G = Grab Sample

Notes:

U = Not detected at a concentration greater than the reporting limit shown
-- = constituent was not analyzed
ft MSL = feet above mean sea level
Methane, ethane and ethene are reported in micrograms per liter (ug/l)
Dissolved hydrogen is reported in nanomoles per liter (nM)
All other constituents are reported in milligrams per liter (mg/l)
Methane, ethane, ethene and dissolved hydrogen analyzed using Method AM20GAX by Pace Analytical (formerly Microseeps), Pittsburgh, Pennsylvania
Metabolic acids analyzed using Method AM21G by Microseeps
Nitrate, sulfate and chloride analyzed by Method 300.0; and total iron analyzed by Method 6010
Dissolved organic carbon (DOC) analyzed by Method 415.1/9060
Carbon dioxide (CO2), hydrogen sulfide (H2S), alkalinity and ferrous iron (Iron 2+) analyzed in field using HACH analytical methods

Sample Type:
K = Split sample

Notes:

VOC = Volatile Organic Compound
PCE = Tetrachloroethene; TCE = Trichloroethene; TCA = Trichloroethane; DCE = Dichloroethene; DCA = Dichloroethane; VC = Vinyl chloride; CET = Chloroethane; CMT = Chloromethane; CFM = Chloroform; MCL = Methylene chloride; CBN = Chlorobenzene; DCB = Dichlorobenzene; CT = Chlorotoluene; DCPE = Dichloropropene; DCPA = Dichloropropane; TCB = Trichlorobenzene; BDM = Bromodichloromethane; Freon-11 = Trichlorofluoromethane; Freon-113 = Trichlorotrifluoroethane.

Samples analyzed by EPA Method 524.2.
Only analytes historically detected most frequently in one or more samples are listed.
All concentrations are reported in micrograms per liter (µg/L).
U = Not detected at a concentration greater than the reporting limit shown.
J = Detected at an estimated concentration between method detection and laboratory reporting limits.
ft MSL = feet above mean sea level.

Sample Type:
K = Duplicate (split) groundwater sample

Notes:
VOC = Volatile Organic Compound
TMB = Trimethylbenzene; NBB = n-Butylbenzene; SBB = sec-Butylbenzene; TBB = tert-Butylbenzene; NPB = n-Propylbenzene; ISB = Isopropylbenzene; PIT = p-Isopropyltoluene; NAP = Naphthalene; MTBE = Methyl tert-butyl ether; CDS = Carbon disulfide; 2BN = 2-Butanone; MIBK = Methyl isobutyl ketone

Samples analyzed by EPA Method 524.2 (drinking water equivalent) except 1,4-dioxane, which was analyzed by EPA Method 8270M.
Only analytes historically detected the most frequently in one or more samples are listed.
All concentrations are reported in micrograms per liter (µg/L).
U = Not detected at a concentration greater than the reporting limit shown.
J = Detected at an estimated concentration between method detection and laboratory reporting limits.
ft MSL = feet above mean sea level.

Sample Type:
K = Duplicate (split) groundwater sample

Table 10
Groundwater Analytical Results - Total Petroleum Hydrocarbons (TPH)
Third Quarter 2014 Groundwater Monitoring Report

Area/ Well ID	Screened Interval (ft MSL)			Sample Date	Sample Type	TPH-CC
D2						
D2-UBe12	4.2	to	-5.8	7/25/2014		300 U
				7/25/2014	K	300 U
D2-UBe13	3.6	to	-6.4	7/25/2014		750

Notes:

TPH - CC = TPH-carbon chain identification, quantified as diesel, between C8-C40
All concentrations are reported in micrograms per liter (ug/l).
All samples analyzed by EPA Method 8015M.

U = Not detected at a concentration greater than the reporting limit shown
ft MSL = feet above mean sea level

Sample Type:
K = Split sample

Notes:

Samples analyzed by EPA Method 200.7 and EPA Method 245.1 (mercury).
All concentrations are reported in micrograms per liter (µg/L).
U = Not detected at a concentration greater than the reporting limit shown.
J = Detected at an estimated concentration between method detection and laboratory reporting limits.
ft MSL = feet above mean sea level.

Appendix A
Geology and Hydrogeology

Appendix A
Geology and Hydrogeology

This section presents regional and Site geology and hydrogeology as interpreted from previous Site investigations.

A.1 Regional Geology

The Site is located in the Los Angeles Basin, which is at the juncture of three southern California physiographic provinces: the Transverse Ranges to the north, the Peninsular Ranges to the east and southeast, and the continental borderland to the west (Wright, 1991). The basin is in an alluvial lowland that slopes gently to the south and is bordered by highlands and their foothills. The basin occupies a structural depression in which deposition has occurred since the late Cretaceous.

The relief of the present basin floor began forming during the middle-Miocene period, and has since been filled with both marine and continental sediments. Primarily fine-grained marine sediments were deposited during marine transgressions while coarse-grained continental sediments were deposited during marine regressions. Fine-grained marine deposits typically form aquitards, whereas stream deposits from the surrounding uplifted areas (San Gabriel Mountains, Santa Ana, and Puente Hills) and coarser marine deposits form aquifers (Yerkes, et. al., 1965).

More specifically, the Site is located in a lowland that is designated as the Ballona Gap. The lowland lies between the Beverly Hills and the Baldwin Hills and extends to the coast and the southerly adjacent Ballona Bluffs (Poland et al, 1959; Barrows, 1974). The Ballona Gap resulted from erosion by the ancestral Los Angeles River.

The generalized Los Angeles Basin stratigraphy described below is based on descriptions presented by Yerkes, et. al., 1965; California Department of Water Resources (DWR), 1961; Poland, et. al., 1956; Poland, et. al., 1959; and Blake, 1991. From youngest to oldest (or shallowest to deepest), the formations encountered are:

Recent alluvium. These deposits consist primarily of unconsolidated stream gravel, sand, silt, and clay with some interbedded littoral and estuary or bay sediments near the ocean. The Recent alluvium includes the Bellflower aquiclude and Ballona aquifer.

San Pedro formation. Silt, clay, sand, and gravel comprise this formation. This deposit, dating from the upper Pleistocene, represents the transition from neritic to non-marine deposition. The San Pedro formation includes the Silverado aquifer.

Pico formation. This marine-derived (bathyal and neritic) formation is composed of poorly consolidated micaceous siltstone and claystone, interbedded with shale and sandstone. The Pico formation is upper Pliocene to upper Pleistocene in age. The upper portion of the Pico formation contains potable groundwater with mid and lower portions of the formation containing saline groundwater (Poland, et. al., 1959).

A.2 Regional Hydrogeology

The Site is located within the Santa Monica Basin, a sub-basin of the Los Angeles County Coastal Plain (DWR, 1961). The aquifers and aquitards in the Los Angeles Basin are formations created during the Recent and Pleistocene Epochs. The Recent and Pleistocene deposits are similar in composition, since their depositional environments were similar. The following summarizes the significant hydrostratigraphic units in the vicinity of the Site (DWR, 1961; Poland, et. al., 1959):

Bellflower Aquitard. The uppermost hydrostratigraphic unit beneath the Site is the Bellflower aquitard (Recent alluvium), which is a sequence of low permeability continental, marine and wind-blown deposits consisting primarily of clay and silty clay (DWR, 1961). Although this sequence is regionally classified as an aquiclude (DWR, 1961), Site-specific data indicate that recharge to the underlying aquifer, although minimal, occurs in this sequence. Therefore, the Bellflower aquiclude is considered to be a semi-confining layer and will be referred to as the Bellflower aquitard.

Ballona Aquifer. Below the Bellflower aquitard is the Ballona aquifer (Recent alluvium), which is encountered in the Ballona Gap north of the Ballona Bluffs and merges into the Gage/Gardena aquifer to the southeast. Although the Ballona aquifer is considered Recent in age, at least part of the aquifer may have been deposited in the late Pleistocene. The Ballona aquifer is often times called the “50-foot Gravel" aquifer because it is generally encountered 50 feet below native grade, and primarily consists of stream deposited coarse sand, rounded to sub-rounded gravel, and cobbles with diameters up to 5 inches, of granitic and metamorphic origin. The Ballona aquifer ranges in thickness from less than 10 feet near the coast to 40 feet near Beverly Hills. The base of the aquifer is approximately 40 to 60 feet below mean sea level (MSL) in the vicinity of the Site (DWR, 1961).

Silverado Aquifer. Underlying the Ballona aquifer, the Silverado aquifer was deposited during the Pleistocene Epoch (San Pedro formation). The Silverado is composed primarily of marine and non-marine sand and gravel. The Silverado can be up to 500 feet thick in parts of the Los Angeles Basin. Locally, the elevation of the base of the aquifer is estimated to be approximately 200 feet below MSL (DWR, 1961).

A.3 Site Geology

Site geologic conditions have been determined based on lithologic logs from numerous monitoring wells and soil borings and from published reports of regional and local geology (McLaren Environmental Engineering [MEE], 1987). The Soil and Groundwater Remediation Plan for the Campus Area (Campus RP) (CDM, 2002c) published four cross-sections of the eastern portion of the Site summarizing geologic conditions as recorded during the drilling and monitoring well installation performed by CDM. These units include the Bellflower aquitard and Ballona aquifer of the recent alluvium, and the Silverado aquifer of the San Pedro formation.

Soil borings show that the shallow soil zone consists of fine- to medium-grained sand. The sand is likely derived from water and wind erosion of the sand deposits on the

Westchester Bluffs, and it varies from 2 to 10 feet in thickness (MEE, 1987). The sandy soil deposits are thickest at the base of the Westchester Bluffs and become thinner to the north. The sand is unconsolidated, loosely compacted, and its permeable nature allows downward percolation of fluids. It should also be noted that varying amounts of non-native fill have also been placed on top of native materials to bring some areas of the Site to final grade. The non-native fill materials originated from the Westchester Bluffs, which were used beneath existing buildings, as well as screened imported fill. The lithologic characteristics of these shallow non-native fill materials are variable.

The Bellflower aquitard (Recent alluvium) underlies the surficial sands throughout the Site. The Bellflower aquitard consists mostly of clay and silty sand layers with smaller lenses of clays, silts, and silty sands throughout. The Bellflower aquitard is approximately 10 to 40 feet thick. The upper half of the Bellflower tends to be dominated by clays, and the lower half tends to be dominated by silty/clayey sands. Because of the differences between the upper and lower halves of the Bellflower, the Bellflower aquitard was subdivided into two zones: the "upper Bellflower aquitard," which is comprised of soils that are generally less permeable than the soils in the "lower Bellflower aquitard" zone.

The Ballona aquifer (Recent alluvium) underlies the Bellflower aquitard throughout the Site. The Ballona aquifer consists of mostly well graded to poorly graded sands and gravels. The Silverado aquifer of the San Pedro formation lies unconformably beneath the Ballona aquifer throughout most of the Site.

MEE (1987) postulated that the Charnock fault offset some of the deeper formations in the western portion of Area D, including the Silverado aquifer of the San Pedro formation. This hypothesis was based on regional geological studies by DWR (1961) and Poland, et. al. (1959) identifying the presence of the Charnock fault underlying a portion of the Central Basin. The Charnock fault was thought to act as a partial barrier to groundwater flow in the Central Basin especially in the deeper aquifers (DWR, 1961). However, Davis and Namson found no evidence of the Charnock fault at the Site (Davis and Namson, 2000). After conducting a geophysical study using high-resolution seismic surveys and comparing geologic data from local oil wells and Site monitoring wells, geologic units used as seismic reflectors were found to be continuous across the entire Site to a depth of 4,500 feet. The authors concluded that the Charnock fault may bend east of the Site, be deeper than 4,500 feet at the Site, or may truncate north of the Site. No evidence of faulting at the Site over the past four million years was found.

A.4 Site Hydrogeology

As presented in Section A.2, the hydrogeologic units beneath the Site generally consist of, from top to bottom, thin surficial sands (2 to 10 feet thick), the Bellflower aquitard (about 30 feet thick for the sum of the upper and lower Bellflower aquitard), the Ballona aquifer (about 10 to 40 feet thick), and the Silverado aquifer. The upper and lower Bellflower aquitard are in hydraulic communication with the underlying Ballona aquifer, based on the interpretation of water level data and the presence of Site-originated contaminants in the Ballona aquifer. However, this vertical hydraulic

communication is limited by the low transmissivity of the Bellflower aquitard soils, particularly those belonging to the upper Bellflower aquitard. The Ballona and Silverado aquifers appear to be in direct hydraulic communication and this suggests that they act as a single aquifer.

Appendix B
Site Investigation and Remediation

Appendix B
Site Investigation and Remediation

Areas of concern in Area D were identified during previous investigations as containing potential sources of impacted groundwater. The western Phase 1 areas of concern include the former FSTA, former Bulk Fuel Storage Area (BFSA), former TS2 Area, and former Test Site 3. More recently, two areas in the western Phase 1 area have been investigated including north of the Icon parcels (location of former Test Site 3) and school site as summarized in Section B.3. The eastern Phase 1 portion, called the Campus Area, is comprised of 12 source areas as discussed in Section B.5. The middle area between the two portions of Phase 1, Area D2, is comprised of the six source areas as discussed in Section B.4. Figure 2 shows the approximate locations of the areas of concern in Area D. The following sections summarize investigative and remedial activities conducted in Area D.

B.1 Phase 1 - Former Fire Safety Training Area

The former FSTA was used from the early-1960s to the mid-1980s to train fire fighters to handle chemical and fuel fires. Fire training consisted of igniting chemicals on a mockup of an aircraft in an area surrounded by a one foot-high soil berm (McLaren Environmental Engineering [MEE], 1987). Environmental Engineering and Consulting (EEC) submitted a Remediation Plan (RP) for the former FSTA on December 20, 2002 (EEC, 2002), which summarized the historic investigations and remediation activities in the area. RWQCB approved the FSTA RP during the third quarter of 2004.

Komex-H20 Science, Inc. (Komex) began implementing limited soils excavation and dewatering during the fourth quarter of 2003, concurrently with the construction of the nearby Riparian Corridor (Komex, 2004). Groundwater extraction began at extraction well (EW) FSTA EW-5 during the third quarter of 2004 and has continued through the present. The extracted groundwater is treated at the TS2 remediation system and discharged to the sanitary sewer system under an industrial waste discharge permit from the Los Angeles City Sanitation District.

During the second quarter of 2010, CDM began implementation at the former FSTA of the *Work Plan for Supplemental Investigation and Implementation of Enhanced Anaerobic Bioremediation within Select Portions of the Former Test Site 2 and Former Fire Safety Training Area of the Playa Vista Development, Playa Vista Property* (EAB RP) (CDM, 2008a), as amended (CDM, 2008c), which was approved by the RWQCB on April 6, 2010 (RWQCB, 2010a). Work completed during the second quarter of 2010 included the installation and initial sampling for volatile organic compounds (VOCs) of two monitoring wells screened in the upper Bellflower aquitard and one well screened in the Ballona aquifer. Additionally, four temporary monitoring wells screened in the upper Bellflower aquitard were also installed and sampled for VOCs. During the third quarter of 2010, a primer solution consisting of lactate-amended groundwater was injected into the target treatment areas through direct-push drill rods. This initial step served as a "primer" to stimulate the subsurface biological activity through the addition of lactate, which is a readily metabolized compound.

Approximately two weeks after injecting the primer solution, the second step of the augmentation process consisted of the addition of a food-grade solution of emulsified soybean oil and lactate for the purposes of accelerating the *in-situ* anaerobic dechlorination of certain VOCs in groundwater. To assist with the evaluation of remedial alternatives, two small-diameter, temporary monitoring wells (HP-D929 and HP-D930), screened in the Ballona aquifer, were installed during the fourth quarter of 2010 and sampled quarterly since installation.

The second round of injections of soluble electron donor (i.e., sodium lactate) in the FSTA EAB injection area was performed during the third quarter 2011 to help increase the rate of VOC removal. The additional injections were performed in accordance with recommendations presented in the *Second Quarter 2011 Former Fire Safety Training Area Remediation Progress Report* (CDM, 2011c) and using the same procedures for primer injection that were documented in the EAB Work Plan. To facilitate the injections, seven additional temporary monitoring wells (HP-D941 through HP-D947), screened in the upper Bellflower aquitard, were installed at the beginning of the third quarter of 2011.

A third round of injections of soluble electron donor (i.e., sodium lactate) in the FSTA EAB injection area was performed during the third quarter 2012 to help increase the rate of VOC removal. These injections were performed in accordance with recommendations presented in the *Second Quarter 2012 Former Fire Safety Training Area Remediation Progress Report* (CDM Smith, 2012b) and using the same procedures for primer injection that were documented in the EAB Work Plan. The seven temporary monitoring wells (HP-D941 through HP-D947), screened in the upper Bellflower aquitard and installed in the third quarter of 2011, were used as points to facilitate the third round of injections.

In response to Condition No. 2 of RWQCB's April 6, 2010 conditional approval (RWQCB, 2010a) of the EAB RP, two temporary monitoring wells (HP-D929 and HP-D930) screened in the Ballona aquifer were installed during the fourth quarter of 2010 and sampled quarterly since installation to assist in the remedy assessment of the former FSTA. The assessment was completed by Geosyntec Consultants, Inc. (Geosyntec) with results presented in the report *Remedy Evaluation Report, Southern Phase 1 Residential Area, Playa Vista,* which was submitted to RWQCB in January 2013 (Geosyntec, 2013). The assessment concluded that multiple lines of evidence demonstrate that the remedy (groundwater extraction and monitored natural attenuation [MNA]) is performing as intended in the former FSTA and surrounding area. Given that the groundwater remedy is performing as intended within its area of application, Geosyntec recommended continued operation of the remedy.

B.2 Phase 1 - Former Test Site 2

Former TS2 was used for approximately 30 years for testing aircraft equipment. Materials were stored in drums placed either on racks or directly on asphalt pavement. All facilities, including the pavement, were demolished in November 1986. The *Former Test Site 2 Remediation Plan* (TS2 RP) (CDM, 2002a) summarized previous

investigations and a groundwater remediation pilot test conducted in the area. A number of chlorinated VOCs including 1,1-dichloroethane (1,1-DCA), cis- and trans-1,2-dichloroethene (DCE), and vinyl chloride were detected in soil and groundwater during these investigations.

Miller Environmental, Inc. (Miller) implemented the TS2 RP by excavating soils and installing an *in situ* EAB system between the third quarter of 2002 and July 2003. System operations began in August 2003 and continued (with exceptions noted below) through January 2012, when the latest rebound test began (see below). The EAB system consists of groundwater extraction and reinjection with lactate to promote dechlorination of residual contaminants. Four extraction wells are located within a high permeability perimeter trench, which completely surrounds the injection gallery. During operations, a portion of the extracted water is mixed with lactate and reinjected into an injection gallery while the remainder of the extracted groundwater is treated *ex situ* and discharged to the sanitary sewer. System performance is monitored quarterly as outlined in the *Test Site 2 Remediation Monitoring and Contingency Plan* (MCP) (CDM, 2002d).

The TS2 extraction and reinjection system was not in operation during the second and third quarters of 2006 while rebound testing was being performed. The TS2 *ex situ* groundwater treatment system continued operating to treat influent groundwater from the former FSTA. TS2 extraction well EW-3 was operated intermittently during that time to supply make-up water for the direct injection of lactate at several wells. Groundwater extraction and reinjection resumed operations on October 2, 2006, and continued throughout most of the second quarter 2007.

Beginning in the third quarter of 2007 and continuing throughout most of the second quarter of 2008, cyclical operations of the hydraulic mound and elevated lactate loading (i.e., 2,000 to 3,000 milligrams per liter [mg/l]) were implemented in accordance with recommendations in the *Second Quarter 2007 Test Site 2 Remediation Progress and Waste Discharge Requirements Report (*Second Quarter 2007 TS2 WDR Report) (CDM, 2007c). Cyclical operations are designed to promote the vertical infiltration of lactate-amended groundwater into the deeper regions of the treatment area.

Based on the results from the several prior quarters of monitoring data that confirmed the presence of only very low VOC concentrations at the majority of monitoring locations in the former TS2, reinjection of lactate-amended groundwater throughout the entirety of the infiltration gallery was discontinued on June 17, 2008. Following this date, the TS2 remediation activities were limited to groundwater extraction at the perimeter trench to maintain hydraulic capture and direct injection of lactate at target locations. Direct injection of lactate at target locations was terminated on November 12, 2008, and reinjection of lactate-amended groundwater at the infiltration gallery was re-initiated on November 19, 2008, in accordance with recommendations presented in the *Third Quarter 2008 Test Site 2 Remediation Progress and Waste Discharge Requirements Report* (CDM, 2008b). The reinjection of groundwater at the infiltration

gallery header pipes continued throughout the first quarter 2009 and was recommended to increase the lactate and organic acid concentrations throughout the entire footprint of the infiltration gallery; such increases were desired in preparation of a second rebound testing phase, which was initiated on March 31, 2009, and continued throughout the entirety of the second quarter 2010.

During the second quarter of 2010, CDM began implementation at the former TS2 of the EAB RP (CDM, 2008a,c). Work completed during the second quarter of 2010 included the installation and initial sampling of five monitoring wells. Three of the newly-installed wells are screened in the upper Bellflower aquitard, one is screened in the lower Bellflower aquitard, and one is screened in the Ballona aquifer. Work completed during the third quarter of 2010 consisted of injecting a primer solution of lactate-amended groundwater into the target treatment areas through direct-push drill rods. This initial step served as a "primer" to stimulate the subsurface biological activity through the addition of lactate, which is a readily metabolized compound. Approximately two weeks after injecting the primer solution, the second step of the augmentation process consisted of the addition of a food-grade solution of emulsified soybean oil and lactate for the purposes of accelerating the *in-situ* anaerobic dechlorination of certain VOCs in groundwater.

The operations of the remediation system extraction wells temporarily resumed on August 31, 2010, after implementation of the EAB activities to promote lateral migration of the electron donor towards the perimeter extraction trench. The resumed extraction enhanced the benefits of the slow-release electron donor addition by increasing the lateral zone of treatment from each injection location.

In response to Condition No. 2 of RWQCB's April 6, 2010 conditional approval (RWQCB, 2010a) of the EAB RP, eight small-diameter, temporary monitoring wells (six screened in the lower Bellflower aquitard and two screened in the Ballona aquifer) were installed during the fourth quarter of 2010 and sampled quarterly since installation to assist in the characterization of groundwater conditions in the vicinity of monitoring well C-91 (CDM, 2010a). The assessment was completed by Geosyntec with results presented in the report *Monitored Natural Attenuation Evaluation Report for the Former Test Site 2 Area,* which was submitted to RWQCB in April 2012 (Geosyntec, 2012). The assessment concluded that multiple lines of evidence demonstrate that the MNA remedy is performing as intended in the C-91 remedy area. Geosyntec's findings also concluded that the existing monitoring well network is adequate for monitoring plume stability. However, Geosyntec concluded that quarterly monitoring was not necessary because annual monitoring would be sufficient to evaluate long-term VOC trends. Therefore, a decrease in sampling frequency was recommended.

During the third quarter 2011, and in accordance with recommendations presented in the *Second Quarter 2011 Test Site 2 Remediation Progress and Waste Discharge Requirements Report* (CDM, 2011d), reinjection activities were temporarily resumed for approximately six weeks to further reduce groundwater conditions in this area and promote VOC dechlorination. Groundwater extraction continued at the extraction

wells throughout the fourth quarter of 2011 but was discontinued on January 17, 2012, to begin rebound testing in accordance with recommendations made in the *Fourth Quarter 2011 Test Site 2 Remediation* System *Progress and Waste Discharge Requirements Report* (CDM Smith, 2012a).

During the fourth quarter 2012, additional injections of a slow-release edible oil substrate (EOS) (i.e., a food-grade solution of emulsified soybean oil and lactate) were performed to further promote the *in situ* bioremediation of groundwater contaminants in the immediate vicinity of well C-156. During these activities, EOS was injected on November 19 and 20, 2012, at three locations surrounding well C-156, which is screened in the lower Bellflower aquitard and located to the north of the perimeter trench.

In preparation of a No Further Action (NFA) determination for unsaturated soil within the former TS2 area, a work plan describing proposed soil and soil vapor sampling activities was submitted to RWQCB on April 25, 2013 (CDM Smith, 2013a). Approval of the work plan to conduct confirmation sampling was subsequently approved by RWQCB on December 23, 2013 (RWQCB, 2013b). Results of the sampling program were submitted to RWQCB in a technical report on January 30, 2014 (CDM Smith, 2014a) and its addendum on February 24, 2014 (CDM Smith, 2014c). The NFA request was submitted to RWQCB on February 24, 2014 (CDM Smith, 2014c). The TS2 NFA for soil only was conditionally approved by RWQCB on May 27, 2014 (RWQCB, 2014a). In accordance with RWQCB's conditional approval of the TS2 NFA, excavation of three impacted areas (with arsenic and/or polynuclear aromatic hydrocarbons) began at the end of the third quarter 2014 and continued into the beginning of the fourth quarter 2014.

Based on the results of the rebound testing, a request to cease groundwater extraction and dismantle the TS2 remediation system was submitted to RWQCB in the third quarter of 2014 (CDM Smith, 2014h).

B.3 Phase 1 Residential Area – Icon Parcels and School Site

Based on the findings of a site assessment conducted by Rincon Consultants, Inc., in August 2010 in the Phase 1 Residential Area (Tract 49104-06 Lots 3, and 8 to 13 [Icon parcels]), RWQCB required Playa to conduct a supplementary groundwater investigation to characterize the nature and extent of VOC-impacted groundwater in the vicinity of the Icon parcels. A work plan was submitted to RWQCB during the fourth quarter of 2010 (CDM, 2010b) and subsequently approved on December 27, 2010 (RWQCB, 2010b). In response to the work plan approval, nine small-diameter, temporary monitoring wells were installed and sampled during the first quarter of 2011 to assess groundwater conditions in this portion of the Site and to monitor potential contamination migrating from the former FSTA. Based on the findings of the initial sampling of the nine temporary wells, one additional permanent monitoring well (C-163), screened in the Ballona aquifer, was installed in the central portion of the Icon parcels during the second quarter of 2011. This well is used to evaluate the

groundwater quality to confirm that the Icon parcel is not a source of groundwater contamination and to monitor potential contamination migrating from the former FSTA. As a condition of the work plan approval (RWQCB, 2010b), RWQCB required that the results of the sampling of the temporary wells be included in the quarterly remediation progress report. Therefore, the nine temporary wells, in addition to the newly-installed well, have been sampled quarterly since the second quarter of 2012, with results presented in this report.

During the first quarter of 2011, a groundwater monitoring well (C-162) screened in the upper Bellflower aquitard was also installed northwest of the former FSTA to monitor groundwater in Bluff Creek Drive north of the school site located in Tract 49104 Lot 6. This well has been sampled quarterly since installation to assess potential trends in order to determine if additional remedial activities are warranted.

Eight groundwater monitoring wells located within the school site and west of the former FSTA were sampled during the third quarter of 2013 and first and second quarters of 2014. These wells were sampled to assist with the evaluation of groundwater flow and contaminant distribution in the vicinity of the former FSTA.

B.4 Phase 2 (Area D2)

Area D2 is located in the central portion of Area D. Characterization activities are summarized in two reports: *Soil and Groundwater Investigation Report, Phase 2 Portion of the Area D Project Area*, which was submitted in May 2002 (CDM, 2002b), and *Soil and Groundwater Investigation Report – Phase II Addendum, Phase 2 Portion of Area D Project Area, Playa Vista Site*, which was submitted to RWQCB on August 6, 2003 (CDM, 2003b). In these reports, six areas were identified as potential areas of concern: the former Salvage Yard Area, the former Firing Range Area, the former Remote Test Site Area, the former Aircraft Service Area, the former Purged Fuel Storage Area, and the former Temporary Drum Storage Area.

A soil and groundwater remediation plan for Area D2 (Area D2 RP) was submitted to RWQCB during the third quarter of 2004 (CDM, 2004b). In accordance with RWQCB's conditional approval of the Area D2 RP, additional soil and groundwater sampling activities were performed in June 2005. Results from the additional investigation activities were presented in the *Addendum 1, Soil and Groundwater Remediation Plan – Phase 2 Portion of Area D Project Area, Playa Vista Site* (RP Addendum), which was submitted to RWQCB on July 15, 2005 (CDM, 2005a). Additionally, an *Area D Remediation Performance Monitoring and Contingency Plan, Playa Vista Site* (PMCP) was also submitted to RWQCB (CDM, 2005b) in July 2005. Supplemental information was submitted to RWQCB in June 2006. On June 1, 2011, an addendum (Addendum 2) to the Area D2 RP was submitted to RWQCB (CDM, 2011b). Addendum 2 was prepared in response to the RWQCB's request for Playa to review the assumptions used to develop the proposed remediation plans in the Area D2 RP, and to confirm that those assumptions were still valid based on data collected since submittal of the Area D2 RP and Addendum 1. A peer review of the Area D2 RP was performed by Hargis +

Associates (Hargis) and submitted to RWQCB on February 22, 2012 (Hargis, 2012). RWQCB revised its June 14, 2012 conditional approval of the Area D2 RP and PMCP on September 13, 2012 (RWQCB, 2012a,b). To assist with groundwater characterization, eleven groundwater monitoring wells were installed in Area D2 during the first quarter of 2011 and have been sampled quarterly since installation. Three wells are screened in the upper Bellflower aquitard (C-157UBe, C-158UBe and C-159UBe), three in the lower Bellflower aquitard (C-157LBe, C-158LBe and C-159LBe), and five in the Ballona aquifer (C-157Ba, C-158Ba, C-159Ba, C-160Ba, and C-161Ba).

During the first quarter 2013, Area D2 remediation system infrastructure (conveyance lines and conduits) were installed between January 7 and March 27, 2013 as part of the Area D2 RP. Area D2 RP implementation continued during second quarter 2013 when 36 performance monitoring, seven remediation system extraction wells, and eight vapor monitoring probes were installed between May 13 and June 7, 2013. Remediation system infrastructure continued to be built throughout the third and fourth quarters of 2013 and was brought on-line in the first quarter of 2014. Quarterly progress updates of the Area D2 remediation system are provided under separate cover by Hargis, with the first quarter 2014 progress report (Hargis, 2014a) being the most recent submission.

Two remediation system extraction wells (D2-RW3LBe and D2-RW4LBe) were installed in July 2014 once Site conditions allowed for the safe installation of the extraction wells. Both wells were successfully incorporated into the remediation system during the third quarter of 2014.

B.5 Phase 1 - Campus Area

The Campus Area was used from the 1940s to the 1990s for the manufacture, research, development, and testing of electronics, aircraft, and other equipment. Historically, structures, asphalt pavement, aircraft taxiways, and a runway covered approximately 80 percent of the Campus Area. A comprehensive list of primary investigation and characterization reports in the Campus Area are summarized in the Soil and Groundwater Remediation Plan – Campus Area (Campus RP) (CDM, 2002c), which was approved by RWQCB in November 2002. These investigations revealed nine source areas (SA). Subsequently, two additional SAs were identified at the project – SA-10 (Isolated Contamination Northwest of SA-1) and SA-11 (former MNA Area 6) (CDM 2007a, b). An additional SA has been identified – SA-12, which includes former MNA Area 7 (CDM, 2011e). The complete listing of SAs in the Campus Area is summarized below and depicted on Figure 2.

- SA-1: Former Underground Storage Tank (UST) South of Former Building 5
- SA-2: Southwest Corner of Former Building 12
- SA-3: Central Area of Former Building 12

- SA-4: Former Drum Storage Area South of Former Building 34
- SA-5: Former UST and Degreaser Pit West of Building 11
- SA-6: Former Building 35
- SA-7: Storm Drain Discharge Northwest of Former Building 12
- SA-8: Sumps, Clarifiers, and Former Vapor Degreaser, Northeast Portions of Buildings 14 and 15
- SA-9: Existing Clarifier and Former Vapor Degreaser Pit, Building 15 Center Bay and Utility Trenches in Building 15 North Bay (Western Portion of Building 15)
- SA-10: Isolated Contamination Northwest of SA-1
- SA-11: Former MNA 6 Area (Southeastern Quadrant of Former Building 6)
- SA-12: Includes the former MNA 7 Area (Southeastern Quadrant of Former Building 20)

The chemicals of concern are generally VOCs for unsaturated soil and VOCs and TPH for groundwater. For soil, the ongoing remedial actions include dual-phase extraction (DPE), soil vapor extraction (SVE), and/or MNA. For groundwater, the ongoing remedial actions include DPE, groundwater extraction, and/or MNA.

A groundwater treatment system was installed north of Building 2 in the Campus Area during the third quarter of 2000 to mitigate a wide range of contaminants, including chlorinated VOCs. This new treatment system began operation in the fourth quarter of 2000. It is typically used on an intermittent, batch basis to treat purge water generated during groundwater monitoring events, or for the treatment of construction dewatering. This system replaced a previous water treatment system operated by Secor International, Inc. (SECOR), which included ten extraction wells (SECOR, 2000). Dewatering and treatment have been summarized in quarterly and annual National Pollution Discharge Elimination System (NPDES) reports, the most recent being the *2013 Annual National Pollutant Discharge Elimination System (NPDES) Report, General NPDES Permit No. CAG914001, Order No. R4-20020-0107* (Playa, 2014). This report contains maps showing specific locations of dewatering points and tables summarizing total volumes of groundwater generated, as well as results of effluent analyses. The treatment system north of Building 2 was disassembled in May 2011 and relocated near Westlawn Avenue and Millennium and will be used as a contingent treatment system for construction dewatering. Currently, purge water generated from the groundwater sampling events are treated by the much larger Campus Area Remediation System (which is described below).

Construction of the Campus Area Remediation System began during the first quarter of 2005 and system startup operations began during the first quarter of 2006.

Remediation System wells consist of DPE and groundwater extraction wells, which are designated "DPE" or "RW", respectively. DPE wells are screened at the first encounter of groundwater (upper Bellflower aquitard) for both soil vapor and groundwater extraction, while groundwater extraction wells are screened in the upper Bellflower aquitard, lower Bellflower aquitard, and Ballona aquifer.

Limited groundwater extraction (less than 100,000 gallons) was initiated on March 7, 2006, and continued intermittently until early April 2006, for the purpose of trouble-shooting the system, but no water was discharged under the NPDES permit CAG914001 until June 2006. The groundwater extraction and treatment system was fully operational and came on-line in June 2006, except at SA-1 (see further description below), where Light Non-Aqueous Phase Liquid (LNAPL) was discovered in September 2005, during construction of the Campus Area Remediation System. Startup operations of the vapor extraction and treatment system began during the third quarter of 2006 and normal operations have continued to the present except for those times when the system periodically had to be shut down for maintenance.

Extraction at two of the SA-1 extraction wells was excluded from the remainder of the Campus Area Remediation System while initial interim remediation measures were implemented to address the presence of LNAPL. Those interim remediation measures included efforts to recover LNAPL from SA1-DPE1 and SA1-RW1be using a vacuum truck, during which time both extraction wells were excluded from the treatment system (CDM, 2007a). CDM then installed a temporary oil-water separator in the vicinity of the SA1-DPE1 and SA1-RW1be wellheads during the early portion of the second quarter of 2007. Groundwater extraction at SA1-DPE1 and SA1-RW1be was initiated on May 7, 2007, and all groundwater was processed through the oil-water separator. The effluent from the oil-water separator was discharged to the Campus Area Remediation System. Starting in May 2007, SA1-DPE1 was operated as a groundwater-only extraction well using a submersible pump. This configuration allowed local oil-water separation in the immediate vicinity of the SA1-DPE1 wellhead that would not have been possible had this well been operated as a DPE well. Continued monitoring of the oil-water separator indicated that only minimal LNAPL was being collected by the oil-water separator, and therefore it was concluded that local oil-water separation was no longer a critical requirement for continued operations of either extraction well. Accordingly, CDM removed the submersible pump from SA1-DPE1 during the first quarter 2008 and initiated DPE operations at this well in accordance with the final remedial action (RD/RA), which was summarized in the Campus RP (CDM, 2002c). During the fourth quarter 2008, extraction at SA1-RW1be was temporary ceased and the oil-water separator servicing this well was removed to accommodate construction activities in the area. Immediately following the completion of these construction activities and for the first two weeks during new pile-driving activities to the immediate north of SA-1, the wellhead was regularly monitored to determine whether local oil-water separation was still warranted. The monitoring efforts revealed an absence of LNAPL and extraction at SA1-RW1be resumed without oil-water separation. Periodic monitoring

for LNAPL continued. A layer of LNAPL was reported at SA1-DPE1 during the second quarter 2011 groundwater sampling activities. Based on this observation, SA1-DPE1 was valved off from the vacuum extraction system. LNAPL was extracted on June 10 and June 13, 2011, using a vacuum truck and disposed off-Site. No LNAPL was observed in water extracted on June 22, 2011. No sheen was observed on June 27 and vacuum extraction was resumed. LNAPL monitoring continues during sampling events to monitor its presence.

On July 16, 2010, the groundwater and vapor extraction systems were shut down so the thermal oxidizer could be disconnected from service and the carbon replaced in the liquid phase carbon vessels. The system was brought back on-line on August 6, 2010.

During the fourth quarter of 2013, eleven temporary monitoring wells (HP-D1050, HP-D1068 through HP-D1070, and HP-D1072 through HP-D1078) constructed with ¾-inch polyvinyl chloride (PVC) casing, with the screened intervals straddling the top of the upper Bellflower aquitard, were installed as part of the larger NFA confirmation sampling program to assess groundwater conditions beneath Parcels 10 and D in the Campus Area (CDM Smith, 2013b, 2013c). Following the initial round of sampling of the temporary wells, eight of the temporary wells were replaced with permanent 2-inch PVC monitoring wells (C-1050, C-1068, C-1070, C-1072, C-1073, C-1075, C-1076, and C-1078) at the direction of RWQCB. The screened interval of the eight permanent wells also straddled the top of the upper Bellflower aquitard. Results from the temporary and permanent monitoring well sampling are presented in the *Request for "No Further Action" Determination for Unsaturated Soils, Parcels 10 and D, Tract 52092 of Campus Area* (CDM Smith, 2013d) and in this quarterly groundwater monitoring report. An NFA determination for unsaturated soils in Parcels 10 and D of the Campus Area was issued by RWQCB on November 26, 2013 (RWQCB, 2013a).

Appendix C
Field and Quality Control Procedures

Appendix C
Field and Quality Control Procedures

C. 1 Field Procedures

The following sections describe the procedures and equipment used to conduct field activities during the third quarter 2014 groundwater sampling event. Quality control procedures are also presented in this section.

Groundwater sampling activities were performed in accordance with the 2006 SAP and CDM Health and Safety Plan (HASP) for the Site (Appendix C). CDM subcontracted Blaine Tech Services Inc. to assist with well purging and groundwater sampling. A CDM geologist was present during sampling and provided oversight throughout the sampling period.

Permanently bound field logbooks with consecutively numbered pages were used to record monitoring and sampling information. These field logbooks are kept in the CDM project file. Field data forms are provided in Appendix D.

C.1.1 Depth to Groundwater Measurements

Prior to gauging, CDM used a Thermo Environmental Instruments Organic Vapor Monitor (OVM) equipped with a photo ionization detector (PID) to monitor organic vapor concentrations at all wellheads. The measurements were recorded on the field data forms. Depth to groundwater was measured according to procedures included in the SAP. The gauging preceded purging or sampling to establish static water levels. Measurements were taken using a Solinst™ water level indicator and recorded on field data forms.

C.1.2 Well Sampling

Field personnel recorded the monitoring well purge data and water level data on field data sheets and in a field logbook. Completed field data forms are included in Appendix D.

Well Purging

Prior to purging, depth to groundwater, total well depth, and dissolved oxygen (DO) were measured at each monitoring well using a decontaminated water level meter and down-hole DO meter. The water column height and well casing volume were calculated based on the depth measurements. The minimum purge volume was calculated as three times the saturated well casing volume.

Monitoring wells and Campus Area DPE wells were purged with external pumps or disposable bailers. Tubing for all the external pumps was dedicated to each well. Most monitoring wells were purged using a decontaminated 1.75-inch diameter Grundfos RediFlo 2™ variable flow submersible pump powered by a portable generator. The intake of the pump was situated close to the middle of the saturated perforated interval.

New, disposable bailers were used to purge wells with conditions that interfered with submersible pump function. These interfering conditions include low water levels, excessive drawdown, silty or very fine sandy water, and wells with fluctuating water levels. All these conditions can deteriorate the function of the variable flow submersible pumps. New, disposable bailers were used for purging and sampling at these wells.

A Waterra pump equipped with dedicated tubing and decontaminated stainless steel or Teflon check-valve was used in the following situations: when wells were sampled for hydrogen, when well diameters were smaller than 1.5 inches, when access required the use of portable equipment, and when LNAPL may have been present. This method of purging was preferred when analyzing for hydrogen because the pump does not induce a hydrogen-generating electric current in the well, which commonly occurs with submersible pumps. The dissolved hydrogen sampling procedures and apparatus were obtained from Microseeps of Pittsburgh, Pennsylvania. The Microseeps sampling protocol is presented in Appendix C. This method was also used when well diameters were too small to use a submersible pump or disposable bailer. Because the only piece of non-dedicated equipment contacting groundwater is the check-valve, the Waterra was used when LNAPL may have been present as a preventative measure against cross-contamination between wells.

A bladder pump was used to purge and sample well C-134 in former TS2. The fluctuating water level in this well prevented the use of the variable flow submersible pump.

When external pumps were used, measurements of pH, electrical conductance (EC), temperature, turbidity, oxidation/reduction potential (ORP), and DO were collected throughout the purging cycle using a flow-through cell. The minimum purge volume was removed from each well and field parameters of the purge water were allowed to stabilize prior to sampling as specified in the field procedures presented in Appendix C. DO was measured again at the end of the purging cycle using Chemetrics® dissolved oxygen ampoules.

Dedicated pumps have been installed in the extraction wells at the Campus Area and former FSTA. The extraction wells at the Campus Area are designated with an "RW" within the name, and the FSTA extraction well is named "EW-5." No external pumps were required to purge the extraction wells. Groundwater was collected directly from the sample ports at the remediation system extraction wells because the wells were already pumping for the remediation system. Sample tubing was connected to the sampling port and a fraction of the flow was allowed to pass through the tubing at a rates ranging from approximately 0.25 to 1 gallons per minute (gpm).

Groundwater Sample Collection

When using a pump for purging, groundwater for analysis was collected directly from the pump's discharge tubing. Sampling was conducted by reducing the flow rate of the pump, then filling the appropriate bottles for analyses according to the field procedures presented in Appendix C. The analytical sampling matrix is

presented in Table 3, and bottles and preservatives for each analysis are shown in Table 4 of this report.

Volatile organic analysis (VOA) vials were filled first, and were checked to ensure no headspace was present, followed by filling sample containers for other unfiltered analyses. The discharge tubing was connected to an in-line disposable groundwater filter when sampling for dissolved organic carbon (DOC) and ferrous iron. Hydrogen sampling was initiated after groundwater samples for other analyses were collected.

When wells dewatered prior to sampling or when bailing was utilized as the purging method, the samples were collected with a new disposable bailer. Samples were collected after the monitoring well had recharged to approximately 80 percent within two hours, or when sufficient volume was available anytime between 2 and 24 hours after dewatering the well. For DOC and ferrous iron analysis, the in-line disposable groundwater filter was attached to the bailer with a freshly-decontaminated threaded Teflon adaptor.

C.1.3 Investigation-Derived Waste (IDW) Disposal

Decontamination water and purged groundwater generated during this monitoring event were transported using a portable tank to the Groundwater Treatment Plant located in the Campus Area for later treatment. Treatment and discharge of water generated during this event was performed in accordance with NPDES Permit No. CAG914001. Purged groundwater was not generated when sampling former FSTA and Campus Area extraction wells as these wells were already in operation at the time of sampling.

C.2 Quality Assurance Procedures

CDM field personnel followed standard quality assurance/quality control (QA/QC) procedures. CDM field personnel were responsible for oversight of the quarterly monitoring field activities, which included the following major tasks:

- Verification of well number and location;
- Sample collection methods, labeling, and preservation of groundwater and surface water samples;
- Complete and accurate record keeping;
- Sampling equipment decontamination;
- Sample transport from the field to the analytical laboratory; and
- Field equipment operation.

C.2.1 Sample Handling

C.2.1.1 Sample Collection

Groundwater samples were collected using the pump or disposable bailer and discharged directly into pre-cleaned, laboratory-provided containers. Surface water

samples from the Riparian Corridor were collected by submerging the sampling container beneath the water surface until the container is full while leaving no headspace. Sample bottles for VOC analyses were filled completely, allowing no headspace. New disposable gloves were donned immediately prior to sampling.

Sample containers and preservatives are summarized in Table 4. Filled sample containers were immediately labeled and placed in an iced cooler for transport to the analytical laboratory.

C.2.1.2 Chain-of-Custody Forms

Samples were delivered to the laboratory at the end of each field day accompanied with a completed chain-of-custody (COC) form. Each COC form included the following information:

- Sample identification;
- Date and time of collection;
- Sample type;
- Analyses required; and
- Signatures of persons involved in the chain of possession, inclusive of dates of possession

Completed laboratory reports and COC forms are included as Appendix F.

C.2.2 Equipment Decontamination

Water level gauging equipment was decontaminated prior to first use at the Site and between sampled wells to prevent cross-contamination. The Solinst™ water level meter was cleaned using a laboratory-grade detergent solution, followed by rinsing with distilled water.

Likewise, down-hole purging equipment was thoroughly decontaminated before first use at the Site and between each well purging to minimize potential cross-contamination. Stainless-steel sampling equipment was decontaminated with a laboratory-grade detergent rinse using a steam cleaner followed by a distilled water rinse. When Grundfos RediFlo 2™ pumps or the bladder pump were used, approximately five gallons of laboratory-grade detergent solution followed by ten gallons of deionized water were pumped through the pump, thereby decontaminating the interior of the sampling equipment. The outside of the sampling equipment was decontaminated using a steam cleaner followed by a distilled water rinse.

If left blank, the parameter was not measured.
NTUs = Nephelometric Turbidity Units
umhos/cm = micromhos per centimeter
mg/L = milligrams per liter
mV = millivolts
* Well dewatered before parameters stabilized or before minimum purge volume was reached
** Reading appears anomalous. Some negative DO readings may be a result of H2S interference in older flow-thru cells.

All wells were purged with a 2-inch Grundfos pump except where noted.
B = Well was purged with a disposable bailer.
W = Well was purged using a Waterra pump.
BL = Well was purged with a bladder pump.
LF = Low-flow purge method
NS = Not Sampled
H = Hand check
G = Grab Sample

Notes:

U = Not detected at a concentration greater than the reporting limit shown
= Probable anomalous DOC result; laboratory not able to complete resolution prior to holding time expiration
-- = constituent was not analyzed
ft MSL = feet above mean sea level
Methane, ethane and ethene are reported in micrograms per liter (ug/l)
Dissolved hydrogen is reported in nanomoles per liter (nM)
All other constituents are reported in milligrams per liter (mg/l)
Methane, ethane, ethene and dissolved hydrogen analyzed using Method AM20GAX by Microseeps, Pittsburgh, Pennsylvania
Metabolic acids analyzed using Method AM21G by Microseeps
Nitrate, sulfate and chloride analyzed by Method 300.0; and total iron analyzed by Method 6010
Dissolved organic carbon (DOC) analyzed by Method 415.1/9060
Carbon dioxide (CO2), hydrogen sulfide (H2S), alkalinity and ferrous iron (Iron 2+) analyzed in field using HACH analytical methods

Sample Type:
K = Split sample
